## 1. Introduction

### 1.1 Objectives

The objective of the G6A algorithm is to take temporal statistics of SGLI Level-3 (L3) spatially-binned geophysical variable (GV) products. The temporal interval of the statistics is 8-day or 1-month. The spatial resolutions are kept the same.

### 1.2 Development strategy

The G6A algorithm is designed to use a same program code for taking statistics of all GVs in order to make the maintenance of the code simple. Basically the input and output of the G6A processing contains the same statistics variables except for the case of snow and ice cover extent (SICE) and cloud type (CLTYPE) in cloud properties (CLPR) product (see next sub-section). The SICE and CLTYPE are flag products and the input and outputs of these two GVs are customized so that the number of snow/ice cover observation or cloud type within each bin with a spatial resolution of 1/24 deg. for SICE and 1/12 deg. for CLTYPE is counted. Finally, to make the addition or deletion of GVs quite easy, the GV names of the statistical targets are defined in an external text file so that the change could be made without compiling the code.

### 1.3 Processing targets and outputs

Processing targets of the L3 GV temporal statistics are all SGLI products for land, cryosphere, ocean, and atmosphere. Input and output variables are summarized in Table 1.

Table. 1 List of the target products, GVs, and output types of the G6A processing

Input Product ID	Long Name	Geophysical Variables (GVs)	Output Product ID	Output Variables*1
<b>RV01</b>	Land surface reflectance	Rs_VN01	<b>RV01</b>	AVE, RMS, N <sub>used</sub> , N <sub>input</sub> , MIN, MAX, Date, QA_flag
<b>RV02</b>		Rs_VN02	<b>RV02</b>	Same as above
<b>RV03</b>		Rs_VN03	<b>RV03</b>	Same as above
<b>RV04</b>		Rs_VN04	<b>RV04</b>	Same as above
<b>RV05</b>		Rs_VN05	<b>RV05</b>	Same as above
<b>RV06</b>		Rs_VN06	<b>RV06</b>	Same as above
<b>RV07</b>		Rs_VN07	<b>RV07</b>	Same as above
<b>RV08</b>		Rs_VN08	<b>RV08</b>	Same as above

<b>RV09</b>		Rs_VN09	<b>RV09</b>	Same as above
<b>RV10</b>		Rs_VN10	<b>RV10</b>	Same as above
<b>RV11</b>		Rs_VN11	<b>RV11</b>	Same as above
<b>RS01</b>		Rs_SW01	<b>RS01</b>	Same as above
<b>RS02</b>		Rs_SW02	<b>RS02</b>	Same as above
<b>RS03</b>		Rs_SW03	<b>RS03</b>	Same as above
<b>RS04</b>		Rs_SW04	<b>RS04</b>	Same as above
<b>RT01</b>		Rs_TI01	<b>RT01</b>	Same as above
<b>RT02</b>		Rs_TI02	<b>RT02</b>	Same as above
<b>RN08</b>		Rs_VN08P	<b>RN08</b>	Same as above

\*1 AVE: Average of valid GV data, RMS: Root Mean Square of valid GV data,  $N_{used}$ : Number of valid GV data actually used in the statistics,  $N_{input}$ : Number of input GV data, Min: Minimum of valid GV data, Max: Maximum of valid GV data, Date: Dates of the SGLI observations during the 8-day or 1-month interval period, QA\_flag: Flag for quality assurance information,  $N_{snow1}$ : Number of snow or ice cover,  $N_{snow2}$ : Number of snow with vegetation or bare ice,  $N_{snow3}$ : Number of melting snow

\*2 Input and output of CLTYPE statistics in the descending orbit is cloud fractions for individual cloud types. The “CFRX” and “cfrx” denotes the cloud fraction of type “x” which is the ID number of the ISCCP cloud classification. For example, in case of “cirrus cloud” the ISCCP ID is “1” and thus the output variable named as “Ncfr1” is stored in the output file with product ID of “CFR1”. In the ascending orbit cloud fraction is estimated for three layer of High, Middle, and Low, the results of which are stored in “CFRH or cfrh”, “CFRM or cfrm”, and “CFRL or cfrlh”, respectively. In addition, cloud fraction considering all the cloud types are also calculated and generated with the ID of “CFRA” and “cfra”.

\*3 Absolute relative azimuth angle (araz) is converted from sensor and solar azimuth angles by  $araz = |sensor\_azimuth - 180.0 - solar\_azimuth|$  and then its statistics (AVE, RMS, MAX, MIN) are calculated and stored in the output file of the G5A processing.

Basically (except for the case of flag products (SICE and CLTYPE)) the statistics variables taken and stored in the output files are the eight values or flag shown in Table1. When processing the flag products, the statistics of Ave, RMS, Min, and Max are not taken. Instead, only snow/ice or cloud counts are stored in the output file.

## 2. Theoretical Description

### 2.1 Processing flow

Figure 1 indicate the flow of the G6A L3 global GV temporal statistics processing. Spatial resolution and array definition of output files are kept the same as the input.

That is, for the processing of land, cryosphere, and ocean products, the resolution is 1/24 deg. and for the atmosphere the resolution is 1/12 deg. The output of G6A processing contains 8-day or 1-month temporal statistics of GV(s) which are stored in one dimensional array. An input file (L3 daily spatially-binned products) contains only one GV and thus the G6A also generates only one output file for the GV. Product ID of the input and output are therefore the same as shown in Table 1.

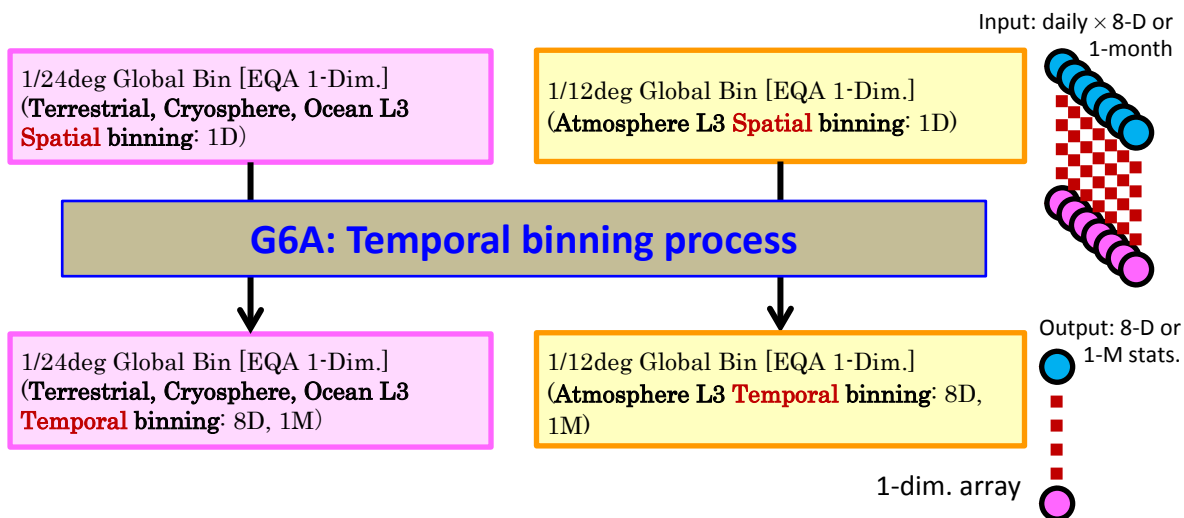

Fig. 1 Flow of the G6A L3 GV temporal statistics processing

## 2.2 Definition of the statistics

Equations for calculating “AVE” and “RMS” are the followings:

$$AVE = \frac{1}{n} \sum_i x_i$$

$$RMS = \sqrt{\frac{1}{n} (\sum_i x_i^2)}$$

Where n is the total number of observation days with valid GVs,  $x_i$  is the daily value of a GV to be processed.

“ $N_{used}$ ” is the number of valid GV data actually used in the statistics, whereas “ $N_{input}$ ” is the number of all the input GV data.

“MIN” and “MAX” are the minimum and maximum of valid GVs data during the temporal interval.

“Date” is an 8-bit value storing the dates of SGLI observations used in the statistics calculation. For example, when the Date value is 40 (i.e., 101000), then SGLI observations of 4<sup>th</sup> and 6<sup>th</sup> days in the temporal interval are used in the statistics.

## 2.3 QA process

“QA\_flag” currently stores flags for discriminating land and water. In future update, QA information for GVs will be included.

#### 2.4. Sample images

Because the output statistics variables are stored in one-dimensional array, the output results cannot be visualized as images. The output one-dimensional array of G6A (and G5A) is projected to the equirectangular (EQR) map projection (and polar stereographic projection only for cryosphere products) in the G7A processing. Figure 2 illustrate the definition of the one-dimensional array of the G6A output.

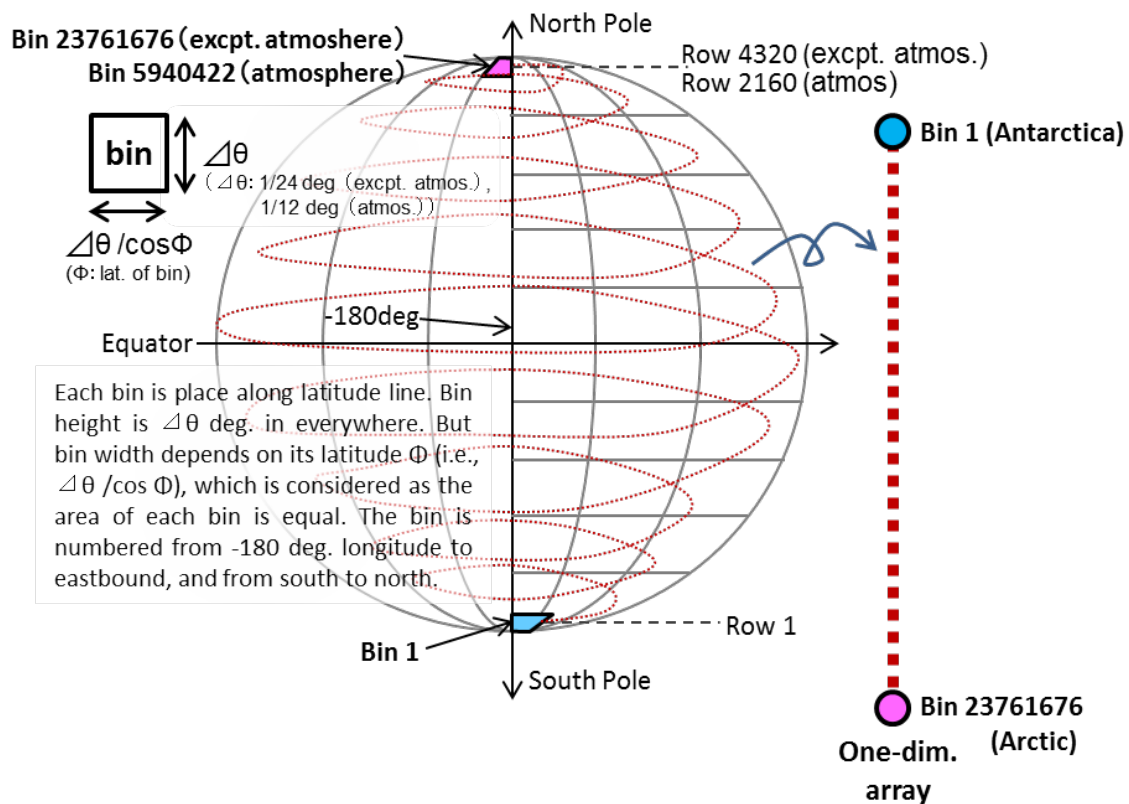

Fig. 2 Definition of the output array of the G6A processing.

#### 3. Current status and remaining issues of the G6A code implementation

The G6A process works well without system errors. Processing speed and memory size are also within the expectations. Remaining tasks are the implementation of the QA\_flag for the output of quality assurance information.
