# 1. Introduction

Aerosols influence the energy budget of the earth's climate system through scattering and absorbing solar radiation. For a more precise estimation of the impact of aerosols on climate systems, investigation of the behavior of aerosols on a global scale is essential but challenging because aerosol amounts and characteristics vary over space and time.

The multiple uses of various imaging sensors on both geostationary and polar-orbiting satellites are helpful to understand a complete picture of aerosol distribution in the global scale. The common algorithm for various sensors over different ground targets (ocean/land) provides more consistent aerosol retrievals over the globe than independent algorithms. Therefore we developed a common retrieval algorithm of the aerosol optical properties to various satellite sensors (Yoshida et al., 2018) based on the method developed by Higurashi and Nakajima (1998) and Fukuda et al. (2013). This approach was applied to GCOM-C/SGLI non-polarization channels.

In addition, aerosol data assimilation studies using satellite data have also been developed to obtain better initial conditions for the aerosol transport model. Since not all parameters can be accurately detected by satellite sensors, and

unrealistic assumptions of aerosol parameters are a major cause of retrieval errors, adding the model information is expected to improve the retrieval accuracy.

In Version2 algorithm, we utilize the forecast of an aerosol transport model for a priori estimates of the retrieval (Yoshida et al., 2020). This allows the aerosol information in the aerosol transport model to be used for retrieval. And by using the assimilated forecast, information from previous satellite observations can be propagated to future retrievals through the aerosol transport model.

The SGLI channels used for the retrieval are given in section 2. The details of the retrieval methodology is explained in sections 3. Details on the candidate aerosol models and lookup table are described in sections 4 and 5, respectively.

## **2. Channels for aerosol retrieval by SGLI**

The SGLI channels used for the aerosol retrieval are listed on Table 1. Only the channels longer than 800 nm are used for the algorithm over ocean to avoid the influence of water-leaving radiance.

Table 1 Channels of SGLI for aerosol retrieval

### 3. Basic principles of the aerosol retrieval algorithm

We developed a common retrieval algorithm to estimate  $\tau$ ,  $\omega$ , and  $\alpha$  from various satellite imagers based on the method developed by Higurashi and Nakajima (1999) and Fukuda et al. (2013). In case of the Lambertian target, the

TOA reflectance  $\rho_i^{sim}$  at a particular channel  $i$  can be approximated by:

$$\rho_i^{sim}(\theta_0, \theta, \varphi) = \rho_i^a(\theta_0, \theta, \varphi) + \frac{t_i^s(\theta_0) \cdot t_i^v(\theta) \cdot \rho_i^s(\theta_0, \theta, \varphi)}{1 - s_i \cdot \rho_i^s(\theta_0, \theta, \varphi)}, \quad (1)$$

where  $\rho_i^a$  is the atmospheric path reflectance, and  $t_i^s$  and  $t_i^v$  represent total

transmittance, from solar to surface and from surface to sensor, respectively.  $s_i$  is the spherical albedo for the illumination of the atmosphere from below, and  $\rho_i^s$  is the surface reflectance. Here,  $\theta_0$  is the solar zenith angle,  $\theta$  is the satellite zenith angle, and  $\varphi$  represents the solar/satellite relative azimuth angle. Parameters  $(\rho_i^a, t_i^s, t_i^v, s_i)$  in eq. (1) can be precomputed as a function of geometries  $(\theta_0, \theta, \text{and } \varphi)$  for each candidate aerosol model that is defined by the aerosol parameters  $(\tau, \text{external mixing ratio of dry volume concentration for fine particles } \eta_f, \text{ and imaginary part of refractive index for fine mode } m_i)$  using a radiative transfer code called System for the Transfer of Atmospheric Radiation whose development was initially lead by the University of Tokyo (STAR, Nakajima and Tanaka 1986, 1988; Stamnes et al. 1988). Additionally, the calculated values are saved as lookup tables. Details on the setting of candidate aerosol models and lookup tables are described in section 4 and 5, respectively.

Figure 1 depicts the flowchart for our algorithm, which estimates three aerosol parameters; namely,  $\tau$ ,  $\eta_f$ , and  $m_i$ . Finally, we calculated  $\alpha$  and  $\omega$  by applying the three derived parameters  $(\tau, \eta_f, \text{ and } m_i)$  to the aerosol model that was described in section 4. Here, the spectral dependence of aerosol optical thickness and single scattering albedo is assumed in the candidate aerosol

model by setting the aerosol parameters, such as size distribution and refractive index.

In the retrieval process, we initially calibrated the observed TOA reflectance using the vicarious calibration coefficient “kv0(MOBY+BOUSSOLE)” recommended in JAXA SGLI site ([https://suzaku.eorc.jaxa.jp/GCOM\\_C/data/prelaunch/index\\_cal.html](https://suzaku.eorc.jaxa.jp/GCOM_C/data/prelaunch/index_cal.html)). Then we

selected the clear-sky (i.e., cloud-free) pixel using a cloud detection algorithm developed for GOSAT/CAI, GCOM-C/SGLI, and EarthCARE/MSI (Ishida and Nakajima 2009; Ishida et al. 2011). Further, we corrected the observed TOA reflectance at a channel  $i$  ( $\rho_i^{obs}$ ) for gas absorption at visible to near-infrared wavelengths. Gas correction was conducted for ozone and water vapor due to their amounts varying significantly with time and location. The corrected TOA reflectance corresponding to the US standard atmosphere ( $\rho_i^{obs'}$ ) is given by:

$$\rho_i^{obs'} = \frac{T_i^{O_3(US)} \cdot T_i^{H_2O(US)}}{T_i^{O_3(OMI)} \cdot T_i^{H_2O(GANAL)}} \cdot \rho_i^{obs}, \quad (2)$$

where  $T_i^{O_3(OMI)}$  and  $T_i^{H_2O(GANAL)}$  are the transmission factors for ozone and water vapor at the observation points, respectively, and  $T_i^{O_3(US)}$  and  $T_i^{H_2O(US)}$  are the transmission factors for the US standard atmosphere, respectively. We used the total ozone columns from JMA chemical transport model and the column water

vapor obtained from JMA global analysis (GANAL) data. Transmission factors  $T_i^{O_3}$  and  $T_i^{H_2O}$  were pre-calculated for various total ozone columns ( $O$ ) and column water vapor ( $w$ ). Subsequently, coefficients  $K_i^{O_3}$ ,  $K_{i,1}^{H_2O}$ ,  $K_{i,2}^{H_2O}$ , and  $K_{i,3}^{H_2O}$  were derived from the fitting of eqs. (3) and (4) based on the MODIS Algorithm

Theoretical Basis Document for Collection 005 and 051 (Levy et al. 2007):

$$T_i^{O_3} = \exp(-GK^{O_3}O), \quad (3)$$

$$T_i^{H_2O} = \exp(-\exp(K_{i,1}^{H_2O} + K_{i,2}^{H_2O} \ln(Gw) + K_{i,3}^{H_2O} (\ln(Gw))^2)), \quad (4)$$

where the air mass factor ( $G$ ) is a function of the solar ( $\theta_0$ ) and the sensor zenith angle ( $\theta$ ), such that:

$$G = \frac{1}{\cos(\theta_0)} + \frac{1}{\cos(\theta)}. \quad (5)$$

Next, we derived the aerosol parameters ( $\tau$ ,  $\eta_f$ , and  $m_i$ ) using an optimal estimation method (Rodgers 2000). The state vector of a set of aerosol parameters  $\mathbf{x} = \{\tau, \eta_f, m_i\}$  was derived by minimizing the object function  $J$  (Eq. 6). It uses the measurement vector of a gas-corrected observed reflectance set  $\mathbf{R} = \{\rho_i^{obs}, i = 1, \dots, N\}$  and simulated TOA reflectance  $\mathbf{F}(\mathbf{x}) = \{\rho_i^{sim}, i = 1, \dots, N\}$  that is calculated using eq.(1), where  $N$  is the channel number.

$$J = [\mathbf{R} - \mathbf{F}(\mathbf{x})]^T \mathbf{S}_e^{-1} [\mathbf{R} - \mathbf{F}(\mathbf{x})] + [\mathbf{x} - \mathbf{x}_a]^T \mathbf{S}_a^{-1} [\mathbf{x} - \mathbf{x}_a] \quad (6),$$

where  $\mathbf{x}_a = \{\tau_a, \eta_{f_a}, m_{i_a}\}$  is the vector of a prior estimate of  $\mathbf{x}$ , and  $\mathbf{S}_e$  and  $\mathbf{S}_a$  are the covariance matrices of  $\mathbf{R}$  and  $\mathbf{x}_a$ , respectively. The  $\mathbf{S}_e$  is given as:

$$\mathbf{S}_e = \begin{bmatrix} \sigma_1^2 & & 0 \\ & \ddots & \\ 0 & & \sigma_N^2 \end{bmatrix}, \quad (7)$$

where  $\sigma_i$  is the uncertainty in TOA reflectance. Since  $\sigma_i$  is mainly induced from sensor noise ( $\sigma_n$ ) and uncertainty in the estimated target land/ocean-surface reflectance ( $\Delta\rho_i^s$ ), we estimate  $\sigma_i$  using eq. (8), as follows:

$$\sigma_i^2 = \sigma_s^2 + \sigma_n^2, \quad (8)$$

where  $\sigma_s$  is the uncertainty in the TOA reflectance that results from  $\Delta\rho_i^s$ . We assume  $\Delta\rho_i^s$  to be some percentage of the surface reflectance ( $\rho_i^s$ ) at each channel. We then apply canonical correlation analysis to find the optimal coordinate system, and converted  $\mathbf{R}$ ,  $F(x)$ , and  $\mathbf{S}_e$  to the coordinate system whose dimension is reduced to the number of retrieved parameters (three).

In the Version1 algorithm, we used spatially and temporally constant values of  $\mathbf{x}_a$ , and  $\mathbf{S}_a$  that are derived from climate analysis, and assumed that the non-diagonal component of covariance matrices was set to 0 (Yoshida et al. 2018). In the Version2 algorithm, to introduce more realistic a prior estimate and covariance into the retrieval process, we employ the forecast from aerosol assimilation system of the Advanced Himawari Imager (AHI) onboard Himawari-8 instead of the constants (Yoshida et al.,2020). In the Himawari-8/AHI aerosol assimilation system, Level3 aerosol optical thickness from

Himawari-8/AHI (Kikuchi et al., 2018) is assimilated into a global aerosol transport model by the 2D-Var assimilation system (Yumimoto et al. 2018). For the aerosol transport model, we use MASINGAR (Model of Aerosol Species IN the Global Atmosphere; Tanaka et al. 2003; Tanaka and Chiba 2005) developed at the Meteorological Research Institute (MRI) of the Japan Meteorological Agency (JMA). MASINGAR covers the major tropospheric aerosol components (i.e., black and organic carbon, mineral dust (10-size bins), sea salt (10-size bins), sulfate aerosols)) and their precursors (e.g., sulfur dioxide (SO<sub>2</sub>), dimethyl sulfide, terpenes)), and is coupled online with an atmospheric general circulation model (MRI-AGCM3; Yukimoto et al. 2012). The detailed method to calculate  $\mathbf{x}_a$ , and  $\mathbf{S}_a$  from the aerosol assimilation system are described in Yoshida et al., 2020. Finally, the optimal solution of  $\mathbf{x}$  that minimizes  $J$  (Eq. 6) was searched by Levenberg-Marquardt Method.

The uncertainties of the three aerosol parameters ( $\tau$ ,  $\eta_f$ , and  $m_i$ )  $\mathbf{S}_{\hat{\mathbf{x}}}$  were calculated using the law of error propagation, as follows:

$$\mathbf{S}_{\hat{\mathbf{x}}} = (\mathbf{A}^T \mathbf{S}_e^{-1} \mathbf{A})^{-1}, \quad (9)$$

where  $\mathbf{A}$  is the Jacobian matrix, and  $\mathbf{S}_e$  is same as in eq. (7), whose elements are calculated using eq. (8). The three aerosol parameters ( $\tau$ ,  $\eta_f$ , and  $m_i$ ), for

which the uncertainties exceeded a threshold value, were treated as invalid values.

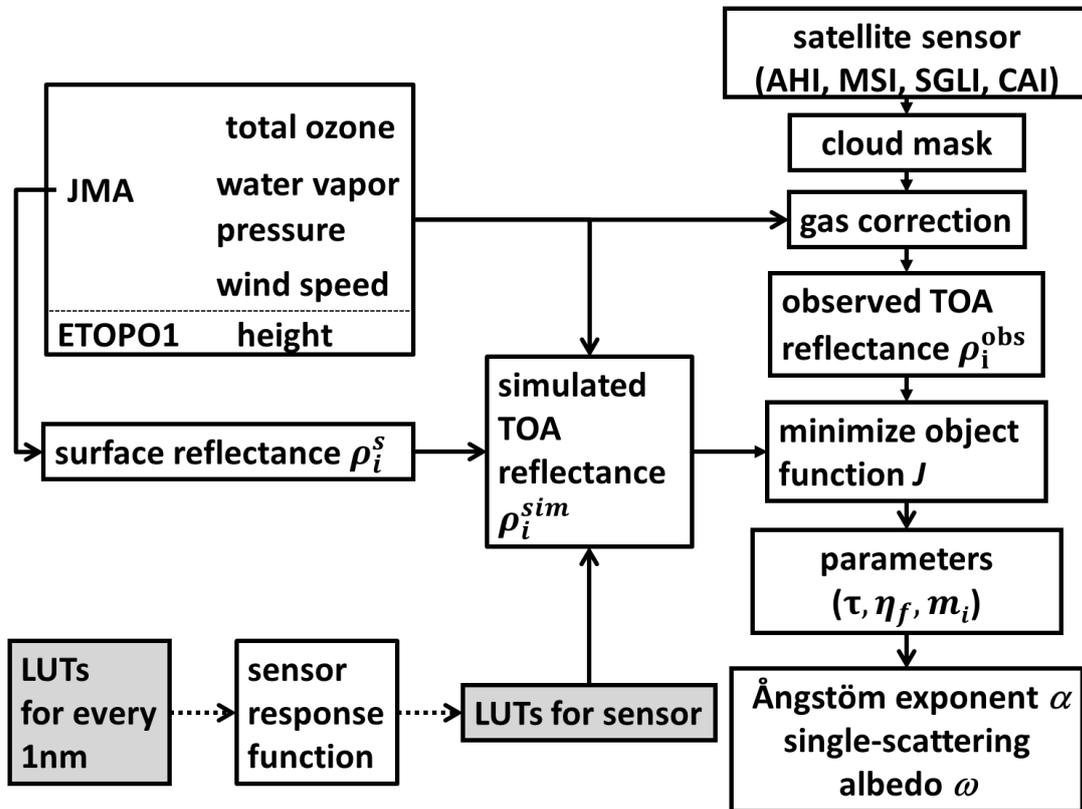

Fig. 1 Flowchart illustrating the retrieval algorithm for L2 aerosol optical properties.

#### 4. Aerosol models

We used common candidate aerosol models over both land and ocean to retrieve aerosols consistently over land and ocean. The candidate aerosol models included aerosol types that were dominant over both ocean and land, and an optimum model was automatically selected. We assumed that the

aerosol model was an external mixture of fine and coarse particles ( $\eta_f$  is the external mixing ratio of the dry volume concentration of fine particles). We set the fine aerosol model based on the average properties of the fine mode for category 1–6 by Omar et al. (2005), which provide the global aerosol models using Aerosol Robotic Network (AERONET) (Holben et al. 1998) measurements. For the coarse aerosol model, we set the external mixture of the pure marine aerosol on the basis of the model that was illustrated by Sayer et al. (2012) and a dust model based on the coarse model of category 1 (dust) that was illustrated by Omar et al. (2005). We define  $\eta_c^{dst}$  as the external mixing ratio of the dry volume concentration of dust particles for the coarse model. Regarding each aerosol size of the fine and coarse models, we used a monomodal lognormal volume size ( $r_d$ ) distribution, which is as follows:

$$\frac{dV(r_d)}{d \ln r_d} = \frac{C_v}{\sqrt{2\pi \ln \sigma}} \exp\left[-\frac{(\ln r_d - \ln r_v)^2}{2 \ln^2 \sigma}\right], \quad (11)$$

where  $C_v$  is the particle volume concentration,  $r_v$  is the volume median radius, and  $\sigma$  is the standard deviation.  $r_v$  is set to 0.143, 2.59, and 2.834 ( $\sigma$  is 1.537, 2.054, and 1.908) for fine, coarse marine, and coarse dust, respectively, based on the observations by Omar et al. (2005) and Sayer et al. (2012). Regarding the aerosol shape, we assumed a spherical model for the fine and coarse marine

model, and a non-spherical model for the coarse dust model. The dust non-spherical parameters were based on a yellow dust model (Nakajima et al. 1989), which employed a semi-empirical theory by Pollack and Cuzzi (1980) with  $r = 1.1$ ,  $x_0 = 7$ , and  $G = 10$  which are parameters of the nonspherical particle scattering theory defined in the original paper. The aerosol vertical distribution was set to the same distribution that was used for rural (dominant at 0–2 km), sea-spray (below 2 km), and yellow sand (4-8 km), for fine, coarse marine, and coarse dust in the STAR code, respectively. The real part of the refractive index was set to 1.439, 1.362, and 1.452 for fine, coarse marine, and coarse dust, respectively, based on Omar et al. (2005) and Sayer et al. (2012). The imaginary part of the refractive index ( $m_i$ ) was set to  $3.0 \times 10^{-9}$  and 0.0036 at all wavelengths for coarse marine, and coarse dust, respectively, based on Sayer et al. (2012) and Omar et al. (2005). However,  $m_i$  for the fine aerosol model was perturbed to represent a nonabsorbing and absorbing aerosol. To decrease the number of derived parameters,  $m_i$  varied with  $\eta_c^{dst}$  such that the fine and coarse models exhibited the same  $\omega$  at 500 nm.

## 5. Lookup Table

To perform model simulations, we used a radiative transfer code called STAR. For rapid processing, we adopted the lookup table method (Higurashi and Nakajima 1999). The parameters  $(\rho_i^a, t_i^s, t_i^v, s_i)$  in eq. (1) were precomputed for 29  $\theta_0$  (0.0, 2.5, 5.0....., and 70.0° ), 25  $\theta$  (0.0, 2.5, 5.0....., and 60.0° ), 37  $\varphi$  (0.0, 5.0, 10.0....., and 180.0° ), 2 pressures (1,013 and 616.6 hPa), 8  $\tau$  (0.0, 0.1, 0.2, 0.4, 0.8, 1.2, 1.6, and 2.0), 11  $m_i$  for fine mode ( $\eta_c^{dst}$  for coarse mode ), and 4  $\eta_f$  (0.0, 0.33, 0.66, and 1.0). We calculated these parameters by the radiative transfer code for every 1 nm from 300 nm to 2500 nm. These high-resolution spectral parameters were then weighted using the response function for each sensor. Thus, we could apply the algorithm to a variety of sensors without recalculation. In this manner, we effectively applied the same algorithm and candidate aerosol models to various satellite sensors.

## 6. Output

Output for SGLI is aerosol optical thickness, angstrom exponent, single scattering albedo, and QA flag. Table 2 shows the descriptions of the QA flag. [A priori used for the retrieval is added to QA\\_flag's attribute.](#)

Table 2 SGLI QA flag, and Mask for statics

	flag	Results	Mask for Statistics
